

### Question1: Object Oriented Programming:

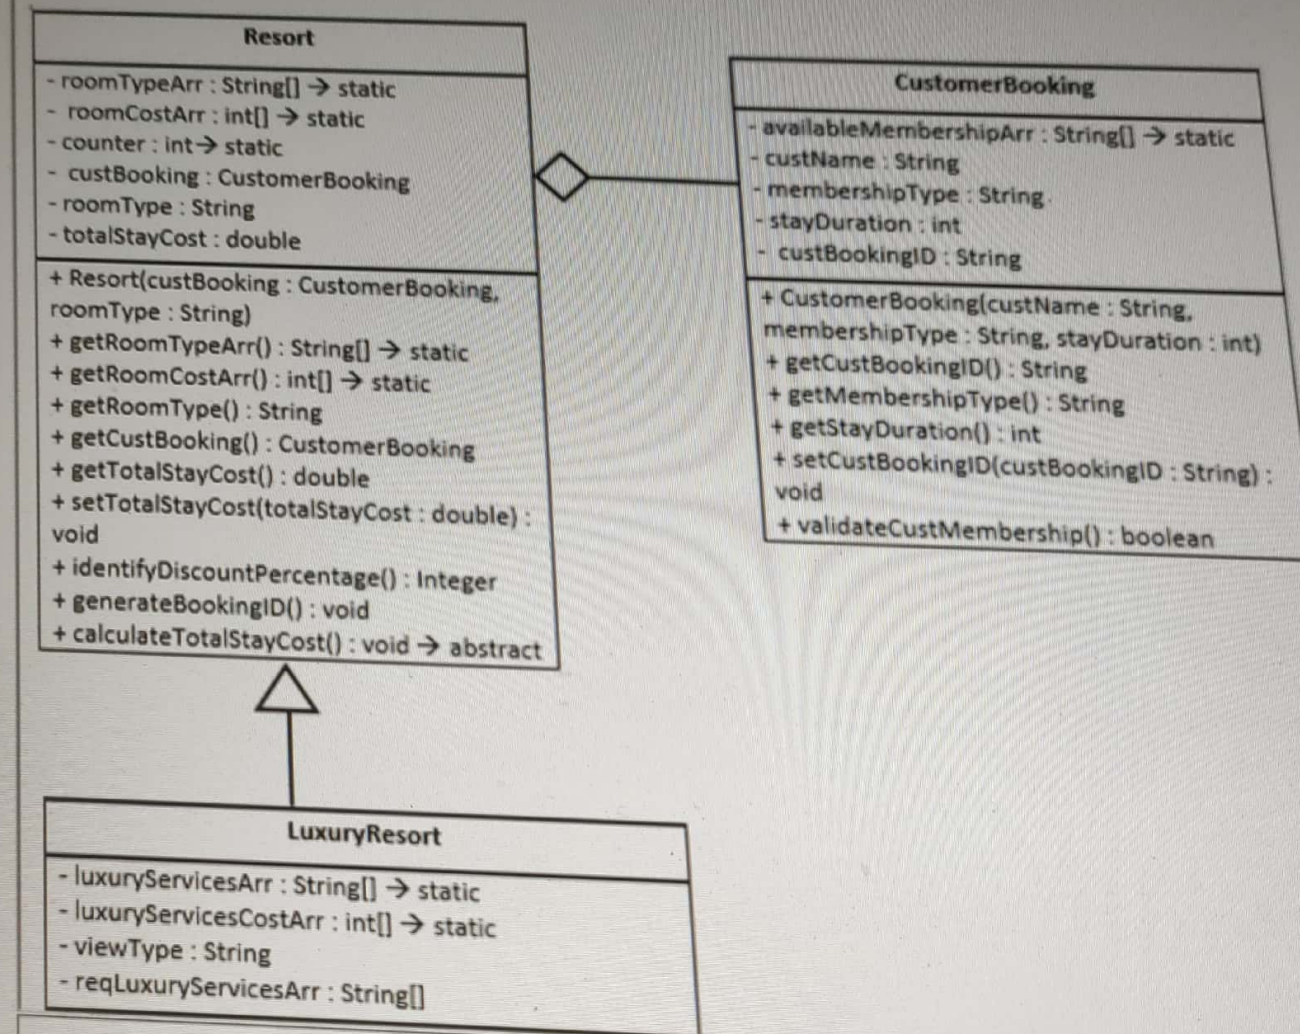

[10 Marks]

#### Description:

Paradise Stay, a popular Resort wants to automate its booking process based on various parameters.

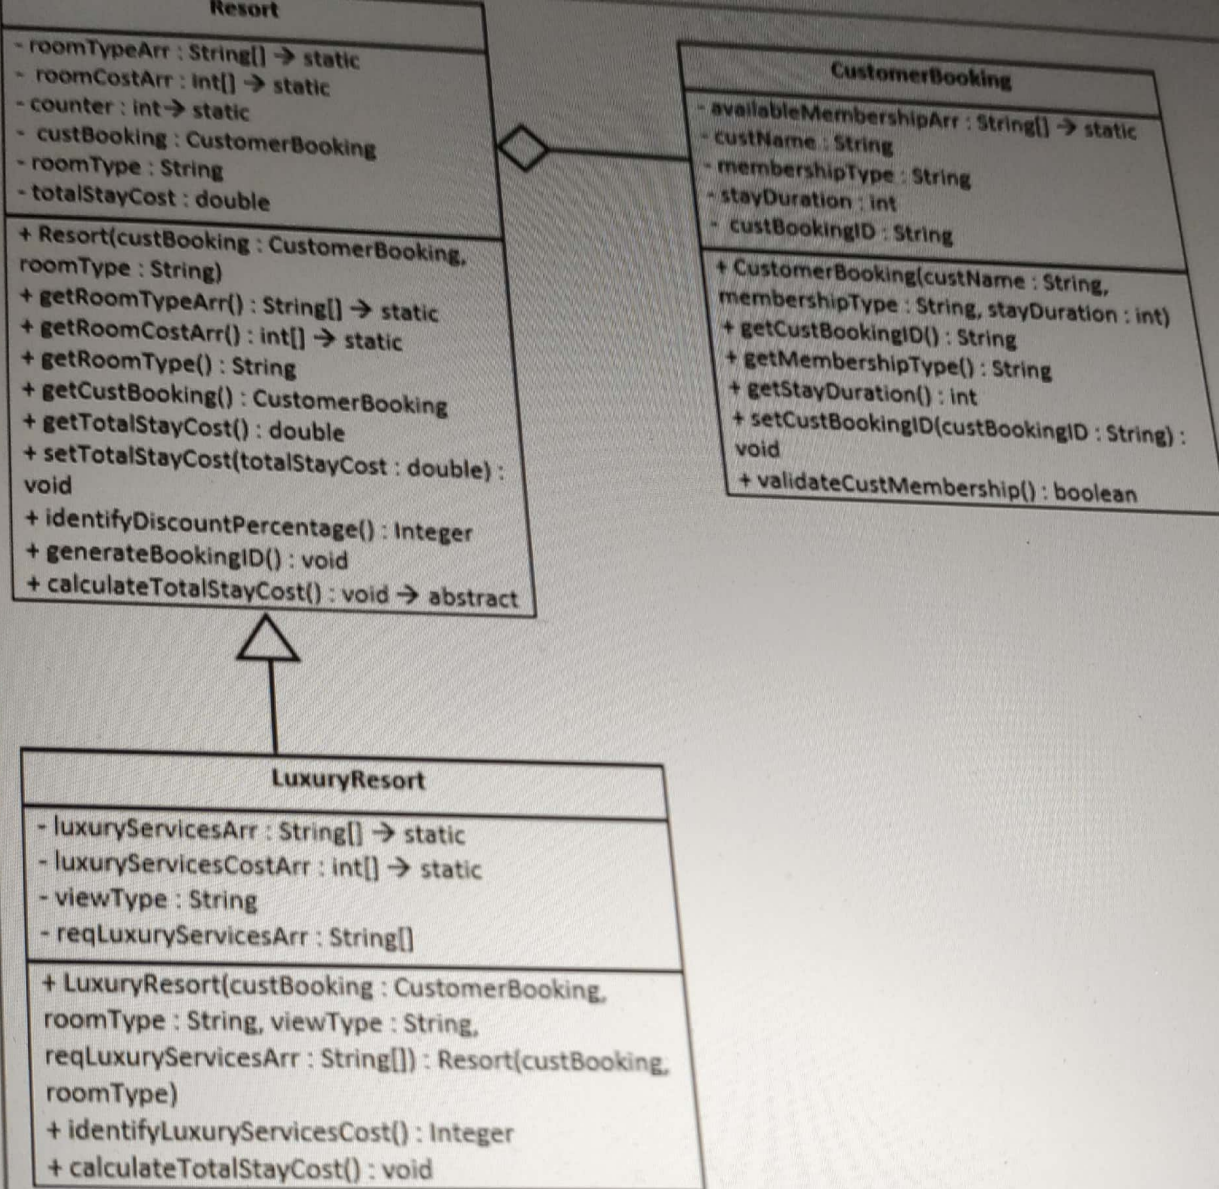

Implement the class diagram given below to achieve the same.

#### Class Diagram:

Type here to search

Notes:

- Do not include any extra instance/static variables and instance/static methods in the given classes
- Case-insensitive comparison is to be done if not explicitly mentioned
- Do not change any value or case of the given variables
- Read notes and examples for better understanding of the logic
- In the derived classes, the order of passing arguments to the constructor would be- base class variables followed by derived class variables

#### Implementation Details:

| Class Name      | Implementation Details |
|-----------------|------------------------|
| Resort          | Partially implemented  |
| LuxuryResort    | Partially implemented  |
| CustomerBooking | Fully implemented      |

CustomerBooking class:

availableMembershipArr:

- It is a static array (String[]) which has *availableMembership* (String) as its elements
- The initial values of the **availableMembershipArr** is as below:

|                        |                         |
|------------------------|-------------------------|
| availableMembershipArr | {"Premium", "Gold", "Pl |
|------------------------|-------------------------|

Note:

|                 |                       |
|-----------------|-----------------------|
| LuxuryResort    | Partially implemented |
| CustomerBooking | Fully implemented     |

**CustomerBooking class:**

**availableMembershipArr:**

- It is a static array (String[]) which has *availableMembership* (String) as its elements
- The initial values of the **availableMembershipArr** is as below:

|                               |                                 |
|-------------------------------|---------------------------------|
| <b>availableMembershipArr</b> | {"Premium", "Gold", "Platinum"} |
|-------------------------------|---------------------------------|

**Note:**

- This array is supplied and hence, no need to code
- Do not change the CASE of the elements in the array

**Resort class:**

**roomTypeArr:**

- It is a static array (String[]) which has *availableRoomType* (String) as its elements
- The initial values of the **roomTypeArr** is as below:

|                    |                                    |
|--------------------|------------------------------------|
| <b>roomTypeArr</b> | {"Regular", "Deluxe", "Executive"} |
|--------------------|------------------------------------|

- This array is supplied and hence, no need to code
- Do not change the CASE of the elements in the array

**roomCostArr:**

- It is a static array `int[]` which has `roomCostPerDay (int)` as its elements
- This array has one-to-one correspondence with the `roomTypeArr`
- The initial values of the `roomCostArr` is as below:

|                    |                           |
|--------------------|---------------------------|
| <b>roomCostArr</b> | <b>{1500, 2500, 3500}</b> |
|--------------------|---------------------------|

**Note:**

- This array is supplied and hence, no need to code

**Example:** If the `roomType` is "Deluxe", then the `roomCostPerDay` would be currency 2500

**identifyDiscountPercentage():**

- This method identifies and returns the `discountPercentage (Integer)` based on the `membershipType (String)` of the customer and the `roomType (String)`
- Refer the below table to identify the `discountPercentage`

| <b>membershipType</b> | <b>roomType</b> | <b>discountPercentage</b> |
|-----------------------|-----------------|---------------------------|
| Basic                 | Standard        | 0%                        |
| Basic                 | Deluxe          | 5%                        |
| Basic                 | Executive       | 10%                       |
| Gold                  | Standard        | 10%                       |
| Gold                  | Deluxe          | 15%                       |
| Gold                  | Executive       | 20%                       |
| Platinum              | Standard        | 15%                       |
| Platinum              | Deluxe          | 20%                       |
| Platinum              | Executive       | 25%                       |

🔍 Type here to search

IdentifyDiscountPercentage():

- This method identifies and returns the *discountPercentage* (Integer) based on the *membershipType* (String) of the customer and the *roomType* (String)
- Refer the below table to identify the *discountPercentage*

| membershipType | roomType    | discountPercentage |
|----------------|-------------|--------------------|
| "Gold"         | "Executive" | 10                 |
|                | "Deluxe"    | 8                  |
| "Platinum"     | -           | 15                 |
| Other values   | -           | 0                  |

Note: Perform case-sensitive comparison for *membershipType* and case-insensitive comparison for *roomType*

Example: If the *membershipType* is "Gold", and *roomType* is "deluxe", then the *discountPercentage* would be 8

generateBookingID():

This method auto-generates and sets the *custBookingID* (String) of *CustomerBooking* class

The *custBookingID* must be prefixed by the first character of *roomType* in uppercase followed by the auto-generated value starting from 101

Subsequent *custBookingID* must be incremented by 1

Use static variable counter appropriately to implement the auto-generation logic

Type here to search

**generateBookingID():**

- This method auto-generates and sets the `custBookingID` (String) of `CustomerBooking` class
- The `custBookingID` must be prefixed by the first character of `roomType` in uppercase followed by the auto-generated value starting from 101
- Subsequent `custBookingID` must be incremented by 1
- Use static variable `counter` appropriately to implement the auto-generation logic

Example: The first `custBookingID` would be "D101" if the `roomType` is "deluxe", the second would be "E102" if the `roomType` is "Executive" and so on

**LuxuryResort class:**

**luxuryServicesArr:**

- It is a static array (String[]) which has `luxuryService` (String) as its elements
- The initial values of the `luxuryServicesArr` is as below:

|                   |                                |
|-------------------|--------------------------------|
| luxuryServicesArr | {"Spa", "Pool", "Inroom-Dine"} |
|-------------------|--------------------------------|

**Note:**

- This array is supplied and hence, no need to code

Type here to search

DELL

**Note:**

- This array is supplied and hence, no need to code
- Do not change the CASE of the elements in the array

**luxuryServicesCostArr:**

- It is a static array (int[]) which has *serviceCost* (int) as its elements
- This array has one-to-one correspondence with the **luxuryServicesArr**
- The initial values of the **luxuryServicesCostArr** is as below:

|                              |                 |
|------------------------------|-----------------|
| <b>luxuryServicesCostArr</b> | {800, 500, 400} |
|------------------------------|-----------------|

**Note:**

- This array is supplied and hence, no need to code

**Example:** If the *luxuryService* required is "Spa", then the corresponding *serviceCost* would be currency 800

**identifyLuxuryServicesCost():**

- This method calculates and returns the *luxuryServicesCost* (Integer)
- If the **reqLuxuryServicesArr** (String[]) is null, then *luxuryServicesCost* would be zero (0)
- Otherwise, For each *service* in the **reqLuxuryServicesArr**,
  - If the *service* is one of the elements in the **luxuryServicesArr**, identify the corresponding *serviceCost* from the **luxuryServicesCostArr**

Type here to search

**Assumption:** Valid values for `reqLuxuryServicesArr` will be null or an array with String elements. Only valid values will be passed

**Note:**

- Perform **case-insensitive** comparison
- No need to validate the assumption

**Example:** If the `reqLuxuryServicesArr` is {"Spa", "Pool"}, then `luxuryServicesCost` would be currency 1300

**calculateTotalStayCost():**

- This method sets the `custBookingID` and calculates and sets `totalStayCost` (double) based on the following logic:
- Invoke the `validateCustMembership()` method of `CustomerBooking` class
- If the above method returns `True` and the `stayDuration` is more than zero,
  - Check if the `roomType` (String) is present as an element in the `roomTypeArr`. If present, identify the corresponding `roomCostPerDay` from the `roomC`
  - Otherwise, `roomCostPerDay` would be -1
  - If the `roomCostPerDay` is not -1,
    - Identify the `discountPercentage` by invoking the `identifyDiscountPercentage()` method

🔍 Type here to search

DELL

- Check if the **roomType** (String) is present as an element in the **roomTypeArr**. If present, identify the corresponding **roomCostPerDay** from the **roomTypeArr**.
- Otherwise, **roomCostPerDay** would be -1
- If the **roomCostPerDay** is not -1,
  - Identify the **discountPercentage** by invoking the **identifyDiscountPercentage()** method
  - Identify the **luxuryServicesCost** by invoking the **identifyLuxuryServicesCost()** method
  - Add the above identified **luxuryServicesCost** to the **roomCostPerDay** to obtain **stayCost** (int)
  - If the **viewType** is "lake", add additional currency 500 to the **stayCost**
  - Identify the **totalStayCost** (int) by multiplying **stayCost** with **stayDuration**
  - Apply the **discountPercentage** on the **totalStayCost**
  - Set the **totalStayCost** (double) with the obtained **totalStayCost**
  - Invoke the **generateBookingID()** method
- Otherwise, set the **custBookingID** to "NA" and **totalStayCost** to -1.0
- Otherwise, set the **custBookingID** to "NA" and **totalStayCost** to -1.0

#### Assumptions:

- The valid values for **viewType** would be "lake" and "garden". Only valid values will be passed
- The **stayDuration** would be in number of days

#### Note:

- No need to validate the assumptions

**Note:**

- No need to validate the assumptions
- Perform **case-sensitive** comparison for **viewType** and **case-insensitive** comparison for **roomType**

**Example:**

If the **custName** is "John", **membershipType** is "Gold", **stayDuration** is 3 days, **roomType** is "deluxe", **viewType** is "lake", **reqLuxuryServicesArr** is {"Spa", "Pool"}, then the **custTotalStayCost** would be currency **11868.0**.

**Question 2: Data Structures**

[5 Marks]

**Problem Statement:**

**Description:** Consider the non-empty **inStrStack** (String Stack) (Top → Bottom) .

Note that each *element* of the **inStrStack** would contain the *itemDescription* followed by '-' followed by *distance* and *priority*. Here, *distance* is represented as 'C' for the order of orders which are far to deliver and have a *priority* 1 or 2

Write a Java program that accepts the above **inStrStack** as input parameter and returns the **outStrQueue** (String Queue) (Front → Rear) based on the below logic:

```

1 package progusingjava;
2
3 //DO NOT MODIFY THE CODE PROVIDED TO YOU
4
5 class CustomerBooking {
6     private static String[] availableMembershipArr = {"Premium", "Gold", "Platinum"};
7     private String custName;
8     private String custBookingID;
9     private String membershipType;
10    private int stayDuration;
11
12    public CustomerBooking(String custName, String membershipType, int stayDuration) {
13        this.custBookingID = null;
14        this.custName = custName;
15        this.membershipType = membershipType;
16        this.stayDuration = stayDuration;
17    }
18
19    public String getCustBookingID() {
20        return this.custBookingID;
21    }
22
23    public String getMembershipType() {
24        return this.membershipType;
25    }
26
27    public int getStayDuration() {
28        return this.stayDuration;
29    }
30
31    public void setCustBookingID(String custBookingID) {
32        this.custBookingID = custBookingID;
33    }
34
35    public boolean validateCustMembership() {
36        for (String membership: CustomerBooking.availableMembershipArr) {
37            if (this.membershipType.equals(membership)) {
38                return true;
39            }
40        }
41        return false;
42    }
43 }
44
45

```
